Abstract

The molecular mechanisms underlying the acquisition of resistance to the antiestrogen Faslodex are poorly understood, although enhanced expression and activity of nuclear factor \( \kappa B \) (NF\( \kappa B \)) have been implicated as a critical element of this phenotype. The purpose of this study was to elucidate the mechanism by which NF\( \kappa B \) up-regulation contributes to Faslodex resistance and to determine whether pharmacologic inhibition of NF\( \kappa B \) by the small molecule parthenolide could restore Faslodex-mediated suppression of cell growth. Basal expression of multiple NF\( \kappa B \)-related molecules in MCF7-derived LCC1 (antiestrogen-sensitive) and LCC9 (antiestrogen-resistant) breast cancer cells was determined, and cells were treated with Faslodex or parthenolide. The effect of these drugs either singly or in combination was assessed by cell proliferation, estrogen receptor (ER)-dependent transcriptional activation, cell cycle analysis, and apoptosis assays. Expression of the p65 NF\( \kappa B \) subunit and the upstream NF\( \kappa B \) regulator \( \kappa B \) kinase \( \gamma \)/NF\( \kappa B \) essential modulator were increased in the resistant MCF7/LCC9 cells (\( P = 0.001 \) and 0.04, respectively). Whereas MCF7/LCC9 cells were unresponsive to Faslodex alone, parthenolide effectively inhibited MCF7/LCC9 cell proliferation and the combination of Faslodex and parthenolide resulted in a 4-fold synergistic reduction in cell growth (\( P = 0.03 \)). This corresponded to a restoration of Faslodex-induced apoptosis (\( P = 0.001 \)), with no observable changes in ER-dependent transcription or cell cycle phase distribution. Because parthenolide has shown safety in Phase I clinical trials, these findings have direct clinical relevance and provide support for the design of clinical studies combining antiestrogens and parthenolide in ER-positive breast cancer. [Mol Cancer Ther 2005; 4(1):33–41]

Introduction

Antiestrogens inhibit the function of the estrogen receptor (ER), a nuclear transcription factor that directs the expression of genes that contribute to proliferation and cell growth (reviewed in refs. 1, 2). The most frequently prescribed is the nonsteroidal antiestrogen tamoxifen, which has been shown to be highly effective in both the treatment of ER-positive breast tumors and in reducing breast cancer incidence in women at high risk for the disease. However, most ER-positive tumors become estrogen independent and develop resistance to antiestrogen therapy, whereas the remainder (~30%) exhibit de novo or intrinsic resistance. Once resistance has developed, treatment with most nonsteroidal antiestrogens is usually unsuccessful.

In contrast, the steroidal antiestrogen Faslodex (ICI 182,780; ICI) induces significant clinical responses in patients whose tumors have acquired tamoxifen resistance (3). The effectiveness of Faslodex in patients with tamoxifen-resistant disease is similar to that of the aromatase inhibitor anastrozole, and several clinical trials have shown that Faslodex may be a viable alternative to nonsteroidal antiestrogens and aromatase inhibitors as a first-line endocrine treatment (4). Faslodex stimulates degradation of the ER and prevents receptor dimerization, inhibiting estrogen-dependent gene transcription (5, 6). As a pure antagonist of the ER, Faslodex is not associated with the increased risk for endometrial cancer that is seen with tamoxifen (7).

The antiestrogen resistance phenotype is complex, involving many changes at the cellular and molecular levels. Antiestrogens are cytostatic, inducing a G\( \text{0-G} \)\( \text{1} \) block in breast cancer cells in culture (1, 8). However, these drugs are also capable of actively inducing programmed cell death or apoptosis, which is consistent with the ability of antiestrogens to increase overall survival (9). One way in which breast cancer cells may become antiestrogen resistant is through changes in gene networks that control cell proliferation and apoptosis (10). To test this hypothesis,
we developed several variant cell lines from the estrogen-dependent and antiestrogen-sensitive MCF-7 breast cancer cells (11, 12). MCF7/LCC1 cells are estrogen independent but remain responsive to antiestrogens; MCF7/LCC9 cells are derivatives of MCF7/LCC1 that have acquired resistance to Faslodex. Similar to what has been observed in breast cancer patients, MCF7/LCC9 cells are cross-resistant to the nonsteroidal antiestrogen tamoxifen (2).

Several genes were found to be altered in the resistant MCF7/LCC9 cells, when their transcriptomes were compared with that of their antiestrogen-sensitive MCF7/LCC1 parental cells by serial analysis of gene expression and microarray analysis (10). For example, we implicated loss of the putative tumor suppressor interferon regulatory factor-1 (IRFI) in acquired resistance and have recently shown IRFI to be a key mediator of the proapoptotic effects of Faslodex in MCF-7 cells (13).

Altered expression of the p65/RelA member of the nuclear factor–xB (NF–B) transcription factor family, which can form functional heterodimers with IFN regulatory factor-1 (14), also was strongly implicated in acquired Faslodex resistance. mRNA levels of p65/RelA are up-regulated 2-fold in the MCF7/LCC9 cells, NF–B-dependent transcription are increased 10-fold, and MCF7/LCC9 cells exhibit a greater sensitivity to the growth inhibitory effects of parthenolide, a small molecule inhibitor of NF–B (10). These data strongly but indirectly implicate NF–B action in acquired antiestrogen resistance.

The NF–B family contains five members that form dimers and regulate the transcription of various genes including cytokines, cell adhesion molecules, the pro-proliferative proteins c-my c and cyclin D1, and several inhibitors of apoptosis (15). Inhibitors of the NF–B pathway show promise as anticancer and anti-inflammatory agents (16). Parthenolide, a sesquiterpene lactone that was first isolated from the feverfew herb (Tanacetum parthenium) native to Central America (17), is a relatively specific small molecule inhibitor of NF–B (18). Parthenolide and other members of the sesquiterpene lactone class have garnered recent attention as promising candidates for cancer treatment either as single agents or in combination with other cytotoxic drugs (19, 20). For example, parthenolide has anti-inflammatory, anticancer, and antiangiogenic properties and has successfully undergone phase I/II clinical trials (21, 22).

Constitutive NF–B activity is widely observed in many tumor types (23), including breast cancer where it is associated with resistance to apoptosis-inducing agents (24). In many tumor lines, autocrine secretion of cytokines and growth factors has recently been implicated in the constitutive activation of NF–B (25). Importantly, NF–B activity also increases in breast cancer cells as they acquire the ability to grow in the absence of estrogen (26, 27). These findings strongly implicate NF–B signaling in the control of breast cancer cell growth and response to antiestrogens.

In this study, we sought to clarify the mechanism by which NF–B up-regulation may affect resistance to Faslodex and determine whether pharmacologic inhibition of NF–B could restore sensitivity to the drug. We show here that in addition to p65/RelA, expression of the upstream regulator NF–B essential modulator/IxB kinase γ (NEMO/IKKγ) is also increased in the resistant cells. The NF–B inhibitor parthenolide efficiently inhibits cell growth and restores sensitivity to Faslodex by synergistically enhancing apoptosis. Our data indicate that inhibition of NF–B may be a successful approach in the treatment of ER-positive breast cancers that have acquired resistance to antiestrogen therapy. NF–B inhibition also may reduce the incidence or delay the onset of antiestrogen resistance. These data provide support for considering the design of clinical studies combining antiestrogens and parthenolide in ER+ breast cancer.

Materials and Methods

Cell Culture and Reagents

MCF-7–derived MCF7/LCC1 and MCF7/LCC9 cells (11, 12) were routinely cultured in phenol red-free improved minimal essential media (IMEM; Biofluids, Rockville, MD) supplemented with 5% charcoal-stripped calf serum (CCS; CCS-IMEM). Cells were maintained in a humidified atmosphere at 37°C and 95% air/5% CO2. Estradiol (estradiol, E2) and parthenolide were purchased from Sigma (St. Louis, MO), and ICI 182,780 (ICI, Faslodex) was a kind gift of Dr. Alan Wakeling (AstraZeneca, Macclesfield, Cheshire, United Kingdom).

Cell Lysis, Immunoblotting, and Immunoprecipitation

Cells were grown in either 10-cm2 dishes or T-75 cm2 tissue culture flasks before lysis. To determine the effects of parthenolide and ICI 182,780 on protein expression, cells were treated with vehicle, 100 nmol/L ICI 182,780 (the IC50 for the control/parental LCC1 cells), or 600 nmol/L parthenolide singly or in combination in CCS-IMEM for 72 hours. Cells were then lysed in modified radioimmunoprecipitation assay buffer [150 mmol/L NaCl, 50 mmol/L Tris (pH 7.5), 1% Igepal CA-630, and 0.5% deoxycholate] supplemented with Complete Mini protease inhibitor cocktail tablets (Roche, Mannheim, Germany) and 1 mmol/L sodium orthovanadate phosphatase inhibitor (Sigma). Lysates were clarified by centrifugation and total protein was quantitated using the bicinchoninic acid assay purchased from Pierce (Rockford, IL). Whole cell lysate (20 μg) was resolved by PAGE using NuPAGE 12% precast gels (Invitrogen, Carlsbad, CA). Proteins were then transferred to nitrocellulose membranes, which were probed with the following antibodies overnight at 4°C: p65 NF–B sc-109 (1:800; Santa Cruz Biotechnology, Santa Cruz, CA), p50 NF–B sc-8414 (1:200; Santa Cruz Biotechnology), p52 NF–B (1:200; Upstate Biotechnology, Charlottesville, VA), IKKγ/NEMO sc-8330 (1:200; Santa Cruz Biotechnology), IxBa sc-371 (1:200; Santa Cruz Biotechnology), phospho-Akt (Ser473; 1:1,000, Cell Signaling, Beverly, MA), or Akt (1:1,000, Cell Signaling). Membranes were then incubated with horseradish peroxidase–conjugated secondary antibodies (Amersham Biosciences, Piscataway, NJ).
for 1 hour at room temperature before enhanced chemiluminescence (Amersham Biosciences) and exposure to film. To confirm equal loading of the gels, membranes were reprobed with antibodies for β-actin (1:5,000; Sigma).

For immunoprecipitations, 400 μg of cell lysate were incubated with 2.5 μL of p65 NFκB antibodies overnight at 4°C with rotation. The following day, 30 μL of Protein A-Sepharose beads (Amersham Biosciences) were added for 1 hour at 4°C to recover the immune complexes, which were then washed twice in modified radioimmunoprecipitation assay buffer, twice in Tris-saline [TN; 50 mmol/L Tris (pH 7.5) and 150 mmol/L NaCl], and resuspended in 2 × Laemmli sample buffer before electrophoresis as described above.

**Cell Proliferation Assays**

MCF7/LCC1 and MCF7/LCC9 cells were seeded at a density of 1 to 2 × 10^4 cells per well in 24-well plates, and 24 hours later were treated with the indicated concentrations of drug in CCS-IMEM. Cells were incubated with the drugs for 7 days, and the media were changed on days 3 and 5. Cells were then trypsinized, resuspended in PBS (Bioluids), and counted using a Z1 Single Coulter Counter (Beckman Coulter, Miami, FL). At least three independent experiments were done in quadruplicate, and data were normalized to vehicle-treated cells. Data are presented as the mean ± SE for a representative experiment.

**Transcriptional Reporter Assays**

The estrogen response element-containing 3xERE-tk-luc reporter plasmid was purchased from Promega (Madison, WI). MCF7/LCC1 and MCF7/LCC9 cells were seeded into 12-well plates at a density of 7 to 8 × 10^4 cells per well. The following day, cells were transfected with 0.4 μg of luciferase reporter plasmid and 0.1 μg pCMV-Renilla (Promega) per well using the FuGENE 6 transfection reagent (Roche, Indianapolis, IN). Three hours post-transfection, media were changed and cells were treated with 100 nmol/L ICI 182,780 and/or 600 nmol/L parthenolide in CCS-IMEM for 24 hours. Subsequently, cells were lysed and activation of the luciferase constructs was measured using the Dual Luciferase Assay Kit (Promega). Luminescence was quantified using a Lumat LB 9501 luminometer (EG&G Berthold, Bundooora VIC, Australia). Luciferase values were normalized to Renilla luminescence, and four independent experiments were done each at least in quadruplicate. Data are presented as the mean ± SE for three independent experiments.

**Apoptosis Assays**

Cells (n = 5 × 10^4) were seeded into 10-cm² dishes 1 day before treatment with 100 nmol/L ICI 182,780 and/or 600 nmol/L parthenolide in CCS-IMEM for 24 hours. Cells were then analyzed for alterations in cell cycle via fluorescence activated cell sorting, which was done by the Lombardi Comprehensive Cancer Center Flow Cytometry Shared Resource according to the method of Vindelov et al. (28). Data are presented as the mean ± SE for three independent experiments.

**Results**

*p65/RelA and NEMO/IKKγ Are Up-Regulated in Antiestrogen-Resistant Cells*

Our previous studies identified a 2-fold up-regulation of p65/RelA mRNA in Faslodex-resistant MCF7/LCC9 cells by expression microarray analysis (10). To confirm altered expression of p65 at the protein level and to examine other NFκB family members and regulatory molecules, whole cell lysates were prepared from MCF7/LCC9 cells and antiestrogen-sensitive MCF7/LCC1 cells and subjected to SDS-PAGE and immunoblot analysis. Similar to mRNA levels, p65/RelA protein is increased ~2-fold in the MCF7/LCC9 cells (Fig. 1A, P = 0.001). In contrast, expression of the p50 subunit of the NFκB heterodimer (Fig. 1B, P = 0.35) or of p52 NFκB2 (data not shown) is not different between the cell lines.

Transcriptional activity of the p65/p50 heterodimer is modulated by the inhibitor IκB, which is in turn negatively regulated by the IKK complex comprised of IKKα, IKKβ,
and the scaffolding protein NEMO/IKKγ (30). To determine whether MCF7/LCC9 cells exhibit changes in these regulatory molecules, lysates were immunoblotted for NEMO/IKKγ and IκBα (Fig. 1C and D). Whereas there is no significant change in IκBα expression (P = 0.10), a significant 2-fold increase in the level of NEMO/IKKγ is apparent in MCF7/LCC9 cells (P = 0.04). NEMO/IKKγ is required for activity of the IKK complex and the inhibitory phosphorylation of IκB in response to inflammatory stimuli that activate NFκB (31), and dysregulation of NEMO is linked to several human pathologies (32). These data suggest that NEMO may also play a role in the response of breast cancer to antiestrogens.

To examine whether the binding of p65 and p50 was altered in antiestrogen-resistant cells, cell lysates were immunoprecipitated with p65 antibodies and immune complexes were captured and subjected to SDS-PAGE as described above (Fig. 1E). No clear differences in p65/p50 complex formation were found between MCF7/LCC1 and MCF7/LCC9 cells.

Independent of the IKK-IκB signaling pathway, NFκB can also be activated by phosphatidylinositol 3-kinase (PI3K); PI3K-mediated activation of Akt can enhance NFκB transcriptional activity without the degradation of IκB (33). Because overexpression of active Akt has also been shown to induce resistance to antiestrogens and cytotoxic drugs (34), MCF7/LCC1 and MCF7/LCC9 cell lysates described above were immunoblotted for phospho-Serine 473 Akt (Fig. 1F). No difference in the level of activated phospho-Akt is observed in the antiestrogen-resistant MCF7/LCC9 cells, suggesting that Akt → NFκB signaling is not the only pathway through which cells can modulate NFκB activation and acquire resistance to Faslodex.

**Inhibition of NFκB by Parthenolide Restores Faslodex Sensitivity to MCF7/LCC9 Cells**

We have previously reported that MCF7/LCC9 cells are more sensitive than MCF7/LCC1 cells to growth inhibition by parthenolide, suggesting that these cells, in which p65/RelA is up-regulated, are more dependent on NFκB-driven cell growth (10). Faslodex (100 nmol/L) approximates the IC50 for proliferation in antiestrogen-sensitive MCF7/LCC1 cells but is ineffective in MCF7/LCC9 cells (Fig. 2A, P = 0.01). To determine whether

Lysates (20 μg) were separated by SDS-PAGE, transferred to nitrocellulose membrane, and immunoblotted. β-actin, loading control. Columns, mean of at least 3 independent experiments; bar, ±SE. Ps were calculated by Student’s t test. E, coimmunoprecipitation of p65 and p50. Lysates (400 μg) were immunoprecipitated with polyclonal anti-p65 antibodies; immune complexes were isolated and separated by SDS-PAGE, transferred to nitrocellulose, and immunoblotted. F, Akt activity is not altered in antiestrogen-resistant MCF7/LCC9 cells. Lysates (20 μg) were separated by SDS-PAGE, transferred to nitrocellulose, and immunoblotted with antibodies specific for phospho-Ser473 of Akt. The membrane was then stripped and reprobed for total Akt.
inhibition of NFκB activity could restore Faslodex sensitivity, MCF7/LCC9 cells were treated with increasing concentrations of parthenolide in the presence or absence of 100 nmol/L Faslodex. In the absence of Faslodex, parthenolide effectively inhibits MCF7/LCC9 cell proliferation with an IC50 of 500 to 600 nmol/L. However, the addition of Faslodex generates a significant nearly 5-fold sensitization, where 50% growth inhibition occurs at a concentration of 100 nmol/L parthenolide (Fig. 2B; \( P = 0.034 \) versus 100 nmol/L parthenolide without Faslodex by Student’s t test; RI = 1.82. 

Parthenolide and Faslodex Synergistically Increase Apoptosis

We subsequently sought to define the mechanism by which parthenolide and Faslodex synergistically inhibit the growth of MCF7/LCC9 cells. A primary action of antiestrogens is to antagonize endogenous estrogen and block ER function; Faslodex can achieve this by affecting receptor turnover (5). We asked whether parthenolide can restore Faslodex-mediated inhibition of ER-dependent transcriptional activity (Fig. 3). MCF7/LCC1 and MCF7/LCC9 cells were cotransfected with an ERE-tk-luciferase reporter vector and the pCMV-Renilla control vector. Three hours post-transfection, cells were treated with estradiol, Faslodex, and/or parthenolide for 24 hours before performing dual-luciferase reporter assays.

MCF7/LCC1 cells exhibit a basal ERE-luciferase activity that is enhanced 8-fold by estradiol treatment and almost abolished by Faslodex. In contrast, MCF7/LCC9 cells express a higher basal ERE-luciferase activity that is slightly enhanced by estradiol but is not inhibited by Faslodex treatment. Whereas transcription from an NFκB-dependent reporter is inhibited by 600 nmol/L parthenolide in MCF7/LCC9 cells (data not shown), parthenolide either alone or in combination with Faslodex has no statistically significant effect on ERE-luciferase activity in MCF7/LCC9 cells, suggesting that the mechanism of their antiproliferative synergy does not involve the regulation of ER-dependent transcriptional events.

Treatment with antiestrogens such as Faslodex can have a cytostatic effect on cell growth, typically manifested as additive inhibition of cell proliferation (\( P = 0.05, \) RI = 1.48). These data strongly suggest that the up-regulated NFκB activity present in MCF7/LCC9 cells is a major contributor to the antiestrogen resistance phenotype.

Figure 2. Parthenolide inhibits the proliferation of antiestrogen-resistant cells and partially restores Faslodex sensitivity. A, MCF7/LCC9 cells are unresponsive to Faslodex. Cells were seeded in quadruplicate and treated with 100 nmol/L Faslodex in CCS-IMEM for 7 d before counting. Columns, mean from a single representative experiment of relative proliferation (relative to vehicle-treated control); bar, ±SE. \( P \) was calculated by Student’s t test. The experiment was independently done at least thrice. B, Faslodex and parthenolide synergistically inhibit MCF7/LCC9 cell proliferation. Cells were seeded in quadruplicate and treated with 0 to 6,000 nmol/L parthenolide in the presence or absence of 100 nmol/L Faslodex in CCS-IMEM for 6 d. Points, mean of relative proliferation; bars, ±SE. *, \( P = 0.034 \) versus 100 nmol/L parthenolide without Faslodex by Student’s t test; RI = 1.82. 

Figure 3. Combined treatment with Faslodex and parthenolide does not inhibit ER-dependent transcriptional activity. MCF7/LCC1 and MCF7/LCC9 cells were transfected in quadruplicate with ERE-tk-luciferase and pCMV-Renilla constructs prior to treatment with 10 nmol/L estradiol, 100 nmol/L Faslodex, and 600 nmol/L parthenolide singly or in combination (or ethanol vehicle) in CCS-IMEM for 24 h. Columns, mean of the ratio of luciferase-to-Renilla activity (relative light units) for four independent experiments; bars, ±SE. \( P < 0.001 \) for all treatment groups by one-way ANOVA.

an accumulation of cells in the G₀-G₁ phase of the cell cycle (1, 8). In some cell systems, parthenolide can arrest cells at the G₀-M phase transition (35). To test whether parthenolide restored the cytostatic activities of Faslodex or induced a G₀-M blockade, MCF7/LCC9 cells were treated with Faslodex ± parthenolide or ethanol vehicle for 24 hours prior to cell cycle analysis (Fig. 4). Parthenolide alone or in combination with Faslodex does not alter the MCF7/LCC9 cell cycle profile, indicating that a block in cell cycle progression does not explain the synergistic reduction in cell growth. Parthenolide and other antiestrogens actively promote apoptosis, and parthenolide has been shown to cooperatively enhance apoptosis induced by other cytotoxic agents such as paclitaxel and 4-hydroxyphenylretinamide (19, 20). Therefore, we measured the effects of Faslodex ± parthenolide or ethanol vehicle on apoptosis as detected by immunostaining for FITC-conjugated Annexin V and propidium iodide staining (Table 1). Approximately 3% of vehicle-treated and 4% of Faslodex-treated MCF7/LCC9 cells undergo apoptosis. In contrast, parthenolide treatment increases the apoptotic fraction to nearly 10%; upon cotreatment with Faslodex and parthenolide, 18% of the cells undergo apoptosis. Importantly, the level of apoptosis seen in the presence of the Faslodex/parthenolide combination was essentially identical to that induced by Faslodex alone in the antiestrogen-sensitive LCC1 cells (Table 1). The strong induction of apoptosis in MCF7/LCC9 cells seen in the presence of both drugs is statistically significant compared with either Faslodex or parthenolide alone (P = 0.001 and P = 0.01, respectively). The calculated RI = 2.28 for the parthenolide/Faslodex interaction indicates synergistic induction of apoptosis in antiestrogen-resistant MCF7/LCC9 cells. Parthenolide stabilizes the inhibitor IκB, leading to the retention of p65 in the cytoplasm in an inactive state (36). Therefore, we measured the effects of Faslodex ± parthenolide or ethanol vehicle on IκBα expression (Fig. 5). Since protein levels of IκBα were unchanged in MCF7/LCC9 cells regardless of treatment, parthenolide may be acting through other alternative mechanisms to synergize with Faslodex and restore the apoptotic response to antiestrogen-resistant MCF7/LCC9 cells.

Discussion

Our previous studies reported the p65/RelA subunit of NFκB as being up-regulated in MCF-7–derived MCF7/LCC9 breast cancer cells that had acquired resistance to Faslodex (10, 11). We have now identified additional changes in the expression of NFκB pathway members in these cells and showed that pharmacologic inhibition of NFκB restores Faslodex sensitivity by markedly enhancing apoptosis. Because the NFκB inhibitor parthenolide is currently being investigated in clinical trials (21), these findings have direct clinical relevance and provide support for the design of clinical studies combining antiestrogens and NFκB inhibitors such as parthenolide in ER+ breast cancer.

Protein expression of the p65/RelA subunit of NFκB is increased ~2-fold in MCF7/LCC9 cells when compared with antiestrogen-sensitive MCF7/LCC1 cells; this agrees with the up-regulation in mRNA levels previously observed (10). However, NFκB-dependent transcriptional activity is elevated almost 10-fold in MCF7/LCC9, implying that other elements of the NFκB signaling pathways are activated in these cells. We found no changes in p50 expression or association with p65; there were also no alterations in expression of p52 NFκB2 (data not shown) or the NFκB negative regulator IκBα. PI3K-dependent signaling can also activate NFκB and Akt activation, a primary downstream target of PI3K, has been implicated in antiestrogen resistance. However, we found no differences in the levels of phospho-Akt, indicating that this pathway also is unlikely to account for the increased NFκB activity.

In contrast, MCF7/LCC9 cells express ~2-fold higher levels of NEMO/IKKγ. NEMO binds to IKKγ and controls the formation of the IKK complex (37); this is required for the activation of NFκB in response to external stimuli such as tumor necrosis factor α (31, 38). Up-regulation of NEMO

in MCF7/LCC9 cells would enhance the kinase activity of IKK and likely adds to the elevated levels of p65 to further increase basal NFκB activation.

Constitutive NFκB activity is known to arise as breast cancer cells progress to an estrogen-independent (26, 27) and antiestrogen-resistant state (10). However, this is the first report implicating NEMO/IKKγ in these events. Regulatory control of NEMO is complex, involving sequential small ubiquitin-like modifier and ubiquitin modification occurring in both the cytoplasm and nucleus (39). Whether the hormonal regulation of NEMO is altered between Faslodex and parthenolide, which generates an estimated RI = 1.82, is synergistic (29). The restoration of presence of only 100 nmol/L parthenolide. This interaction by which NFκB activity is elevated in breast cancer cells with acquired antiestrogen resistance.

The NFκB inhibitor parthenolide strongly represses the proliferation of MCF7/LCC9 cells (100 nmol/L, ineffective; IC50 = 600 nmol/L) and restores their sensitivity to Faslodex. For example, whereas treatment with 100 nmol/L Faslodex alone is ineffective, 50% growth inhibition is achieved in the presence of only 100 nmol/L parthenolide. This interaction between Faslodex and parthenolide, which generates a comparable to that seen when MCF7/LCC1 cells are treated with the same dose of Faslodex (19.9%). Parthenolide can enhance the apoptotic activities of taxanes and retinoids (19, 20), and we now show that it can also potentiate the death of antiestrogen-resistant breast cancer cells by restoring their sensitivity to Faslodex.

DeGraffenried et al. (41) have recently reported that NFκB inhibition by parthenolide increased breast cancer cell sensitivity to tamoxifen. However, these investigators used MCF-7 cells genetically engineered to overexpress activated Akt; these cells exhibit tamoxifen resistance and NFκB activation that is entirely dependent on Akt-mediated pathways. In our cell system, which was derived by selection in the presence of Faslodex rather than by genetic engineering of the cells, NFκB up-regulation does not correlate with enhanced Akt activity.

Sesquiterpene lactones in general, and parthenolide in particular, can prevent the degradation of IκB, block activation of IKK, alkylate cysteine-38 in p65/RelA to prevent DNA binding, and inhibit inducible nitric oxide synthase (36, 42, 43). We found no evidence of IκB stabilization when MCF7/LCC9 cells were treated with parthenolide either in the absence or presence of Faslodex. Parthenolide can also inhibit p42/44 mitogen-activated protein kinase activity (42) but we observed no reduction in the levels of phospho-mitogen-activated protein kinase in our cells upon parthenolide treatment (data not shown). Interestingly, Nakshatri et al. (44) have recently shown that parthenolide can reverse breast cancer cell resistance to tumor necrosis factor-related apoptosis-inducing ligand by enhancing the activation of c-Jun NH2-terminal kinase. Whether parthenolide-induced c-Jun NH2-terminal kinase activity plays a role in its restoration of Faslodex sensitivity in MCF7/LCC9 cells has yet to be determined.
Our studies clearly show that treatment with the NF-κB inhibitor parthenolide is a viable approach to restoring Faslodex-induced apoptosis in breast cancer cells that have acquired resistance. Several preclinical studies have shown that parthenolide also is effective in the treatment or chemoprevention of cancer cell growth (45). A phase I study of feverfew in cancer patients was recently completed and reported no significant toxicity observed at the doses tested (21). Other direct or indirect inhibitors of the NF-κB pathway also show promise as antiproliferative agents (16) and include some nonsteroidal anti-inflammatory drugs, anti-oxidants, immunosuppressants, proteasome inhibitors, and glucocorticoids. Our work now shows that inhibition of NF-κB may also be useful for the treatment of ER-positive breast cancers that have acquired resistance to antiestrogen therapy, thus restoring the activity of one of the most active and least toxic modalities available in the treatment of endocrine-dependent breast cancer.
