**Conflict of Interest:** Authors Angela Wandinger-Ness, Larry A. Sklar, and Laurie Hudson are listed as co-inventors on a US patent application (allowance pending) entitled "Modulators of GTPases and Their Use". The patent is owned by the University of New Mexico and its technology transfer office, STC.unm, and is under an option to license.
Abstract

Cdc42 (cell division control protein 42) and Rac1 (Ras-related C3 botulinum toxin substrate 1) are attractive therapeutic targets in ovarian cancer based on established importance in tumor cell migration, adhesion and invasion. Despite a predicted benefit, targeting GTPases has not yet been translated to clinical practice. We previously established that Cdc42 and constitutively active Rac1b are overexpressed in primary ovarian tumor tissues. Through high throughput screening and computational shape homology approaches we identified R-ketorolac as a Cdc42 and Rac1 inhibitor; distinct from the anti-inflammatory, cyclooxygenase inhibitory activity of S-ketorolac. In the present study, we establish R-ketorolac as an allosteric inhibitor of Cdc42 and Rac1. Cell-based assays validate R-ketorolac activity against Cdc42 and Rac1. Studies on immortalized human ovarian adenocarcinoma cells (SKOV3ip), and primary, patient-derived ovarian cancer cells show R-ketorolac is a robust inhibitor of growth factor or serum dependent Cdc42 and Rac1 activation with a potency and cellular efficacy similar to small molecule inhibitors of Cdc42 (CID2950007/ML141) and Rac1 (NSC23766). Furthermore, GTPase inhibition by R-ketorolac reduces downstream p21-activated kinases (PAK1/PAK2) effector activation by >80%. Multiple assays of cell behavior using SKOV3ip and primary patient-derived ovarian cancer cells show that R-ketorolac significantly inhibits cell adhesion, migration and invasion. In sum, we provide evidence for R-ketorolac as direct inhibitor of Cdc42 and Rac1 that is capable of modulating downstream GTPase-dependent, physiological responses, which are critical to tumor metastasis. Our findings demonstrate the selective inhibition of Cdc42 and Rac1 GTPases by an FDA approved drug-racemic ketorolac that can be used in humans.
Introduction

Ovarian cancer is the leading cause of gynecological cancer deaths in the United States with a 45% 5-year survival rate (1). Often associated with malignant ascites, which facilitates metastasis, most patients are diagnosed at advanced stages with dissemination throughout the intraperitoneal cavity (2). Recent understanding of the etiology of “ovarian cancer” suggests that the majority of serous ovarian cancers originate from dysplastic fallopian tubes (3). Metastatic spread of ovarian cancer beyond the ovary or fallopian tube is mediated by surface shedding of tumor cells and formation of free-floating multicellular aggregates in the ascites fluid. Subsequent mesothelial anchoring and invasion of the submesothelial matrix leads to secondary lesions on peritoneal organs and surfaces (4). Consequently, the first line of treatment involves major debulking surgery to remove as much tumor burden as possible, most often followed by intraperitoneal chemotherapeutic treatment in optimally debulked patients after recovery from surgery. Therefore, targeting tumor cell adhesion, migration and invasion in the perioperative period, during which tumor dissemination may occur and impact ovarian cancer recurrence, presents an important potential window of opportunity for treatment that has not yet been extensively explored (5, 6).

It is well established that Rho-family (Ras homolog) GTPases are central to dynamic actin cytoskeletal assembly and rearrangement that are the underpinnings of normal cell-cell adhesion, cell migration and even transformation (7). Among the Rho-family GTPases, Cdc42 (cell division control protein 42) and Rac1 (Ras-related C3 botulinum toxin substrate 1) are of particular interest on account of their frequent overexpression or hyperactivation in epithelial cancers including ovarian cancer (8-12). In response to extracellular stimuli, Cdc42 and Rac1 GTPase transition from an inactive GDP-bound status to an active GTP-bound status and interact with downstream effectors to propagate changes in cell behaviors (7). For example, activated Cdc42 and
Rac1 phosphorylate p21-activated kinases (PAK1/PAK2) which in turn initiate actin reorganization and subsequently regulate cell adhesion, migration and invasion (13). Furthermore, the Rac1-PAK signaling axis lies immediately downstream of growth factor activated Ras signaling and in ovarian cancer has been shown to modulate epithelial to mesenchymal transition (EMT) and angiogenesis (14, 15). Therefore, it is of interest to investigate the utility of Cdc42 and Rac1 as points of intervention in the intraperitoneal spread of ovarian cancer.

While Cdc42 and Rac1 are potential high value, therapeutic targets in ovarian and other cancers, key gaps remain in translating known GTPase inhibitors into clinical application. Statins are HMG-CoA reductase inhibitors that indirectly act as broad spectrum GTPase inhibitors by interfering with the prenylation required for functionally essential membrane association (16). Cancer risk reductions associated with statin use are reported for breast, colorectal, and pancreatic cancers (17-19). The benefit in ovarian cancer is mixed and subtype specific (20), motivating the identification and testing of more selective GTPase inhibitors. Several GTPase targeted inhibitors have been identified with various modes of action. Yet, irrespective of whether they affect signaling (e.g. NSC23766, secramine) (21, 22), nucleotide binding ability (e.g. CID2950007 (PubChem compound identification for Cdc42 GTPase inhibitor)) (23), or effector binding activity (e.g. Y27632) (24), none have as yet been translated to human use.

Using a combination of high throughput screening and computational simulation, the R-enantiomer of ketorolac was identified as a selective Cdc42 and Rac1 inhibitor, without effect on RhoA (25). Ketonolac is clinically administrated as a racemic mixture for pain relief, based on the activity of S-ketorolac as a dual (COX-1/COX-2) inhibitor (26). The R-enantiomer was considered inert prior to our identification of its Cdc42 and Rac1 inhibitory activity (27, 28). Published literature on breast, lung and kidney cancer patients
and our own data on ovarian cancer patients demonstrates that besides its analgesic function, ketorolac has significant benefit for patient survival (6, 12, 29, 30). The mechanism of this anti-cancer action is not clear, yet appears to be selectively ascribed to ketorolac and not a general property of cyclooxygenase inhibitors or other analgesics and anesthetics (6, 31, 32). This suggests that ketorolac possesses an additional property. In the present study, a human patient immortalized ovarian cancer cell line (SKOV3ip) and primary ascites-derived ovarian cancer cells were used to demonstrate that R-ketorolac acts as an allosteric inhibitor of Cdc42 and Rac1 nucleotide binding activities in vitro and blocks their activation and downstream activation of the PAK signaling axis. As a consequence of the inhibition there is a reduction in ovarian cancer cell adhesion, migration and invasion. Taken together the data demonstrate the potential for repurposing R-ketorolac, an FDA approved drug in the racemic form, for improved patient benefit in progression free and overall survival.

Materials and Methods

Cell and reagents

The human ovarian adenocarcinoma epithelial cell line SKOV3ip was derived from SKOV3 cell line by selecting for a peritoneal metastatic phenotype in the mice and was obtained under a Material Transfer Agreement with MD Anderson in June 24 2009. The ascites derived ovarian cancer cells were obtained from nine patients from 2012 to 2015. SKOV3ip cell line was authenticated using Short Tandem Repeat (STR) analysis (performed by Promega). SKOV3ip cells and primary ovarian cancer cells were cultured in RPMI 1640 media containing 5% FBS (Atlanta Biologicals). All cell culture media and reagents were purchased from Gibco® (Life Technologies). R-, and S-ketorolac were from Toronto Research Chemical Inc. BODIPY-GTP ((4,4-difluoro-4-bora-3a,4a-diaza-s-
indacene or dipyrrromethene boron difluoride) nucleotide analogue) was from Invitrogen Molecular Probes. Rat tail type I collagen was obtained from BD Biosciences. NSC23766 was from Santa Cruz Biotechnology and CID2950007 was from Sigma-Aldrich. GST (glutathione S-transferase)-tagged GTPases were purified as described previously (33). GST-PAK1 protein was from Millipore. A polyclonal antibody directed against Tks5 (Src tyrosine kinase substrate 5) was prepared as described (34). The following commercial antibodies were used: mouse mAb (monoclonal antibody) directed against Rac1 from BD Transduction Laboratories, mouse mAb directed against Cdc42 from Santa Cruz, FITC (fluorescein isothiocyanate)-conjugated mouse mAb directed against EpCAM (epithelial cell adhesion molecule) (clone Ber-EP4) from Dako; rabbit polyclonal Cy5-conjugated anti-CA125 (cancer antigen 125) from Bioss Inc., mouse mAb PE (Phycoerythrin)-conjugated anti-CD45 (lymphocyte common antigen 45) from eBioscience, rabbit polyclonal antibodies directed against phospho-PAK1 (Ser144)/PAK2(Ser141), phospho-PAK1(Ser199/204)/PAK2(Ser192/197), phospho-PAK1(Thr423)/PAK2(Thr402) and PAK1 from Cell Signaling Technology, Alexa 488 goat anti-mouse antibody and Alexa 647 goat anti-rabbit antibody from Life Technology, all used per manufacturers’ instructions.

Patient information

A Phase 0 trial investigating the use of postoperative ketorolac was reviewed and approved by the University of New Mexico Health Sciences Center Human Research Review Committee (NCT01670799 clinicaltrials.gov) (35). Informed patient consent was obtained prior to surgery. Eligible patients having suspected advanced stage ovarian, fallopian tube or primary peritoneal cancer underwent planned optimal cytoreductive surgery. Upon surgical entry into the abdomen, ascites fluid was retrieved and residual material was recovered and sent fresh to the investigators for processing. Ascites
material used for this study was from patients confirmed to have stage III or IV at final pathologic diagnosis. Nine patient samples were included in the study (Supplementary Table 1).

**Isolation and cell culture of ascites-derived primary ovarian cancer cells**

Peritoneal ascites were obtained at the time of debulking surgery with an average volume of 200 ml. Cells were collected by centrifugation at 300g for 5 min. The Ficoll-Paque (1.073 ± 0.001 g/ml) PREMIUM density gradient media (GE Healthcare) was used to pellet and remove erythrocytes and polymorphonuclear cells. The mononuclear white cells and tumor cells found at the top of the Ficoll interface were transferred to a sterile tube and washed with RPMI 1640 media with 5% FBS. To deplete leukocytes and further enrich tumor cells, samples were incubated with CD45-coated Dynabeads® (Life technologies) for 1.5 h at 4 °C, washed and collected by centrifugation according to the manufacturer’s protocol. Isolated tumor cells were cultured as described by T. Shepherd et al (36). Briefly, enriched ovarian cancer cells were cultured on collagen-coated (20 µg/cm²) tissue culture dishes. After 3-4 d, when most of the tumor cells had adhered, the media was replaced and continued to be changed every 2-3 d until cells grew to confluence. The expanded cells were used for filopodia formation, cell adhesion, migration and extracellular matrix degradation assays.

**Synthesis of glutathione (GSH) beads for flow cytometry assay**

High density glutathione (GSH) conjugated beads were synthesized for flow cytometry assays by loading Superdex peptide beads with GSH as previously reported (37).

**Flow cytometric BODIPY-GTP binding assay**
The assay was carried out according to the protocols described previously (37). Briefly, individual GST-GTPases were attached to their respective GSH beads and combined. In the equilibrium assay, $2 \times 10^3$ GSH beads loaded with GST-GTPase were pre-incubated with either DMSO (dimethyl sulfoxide) or a fixed compound concentration for 15 min followed by the incubation with varying concentrations of BODIPY-GTP for 30 min at room temperature. In the dose-response assay, $2 \times 10^3$ GSH beads loaded with GST-GTPase were pre-incubated with DMSO or increasing concentration of the compound for 15 min followed by the incubation with a fixed concentration of BODIPY-GTP for 30 min at room temperature. For measurement, samples were diluted at least 10-fold and delivered and analyzed by the BD FACScan flow cytometer.

**Flow cytometric GTPase effector binding assay for quantification of active, cellular GTPase levels**

The assay was carried out according to the protocols described previously (38). Ketorolac treated and vehicle-control cells were lysed in RIPA (high stringency cell lysis buffer) buffer (50 mM Tris-HCl, 150 mM NaCl, 1 mM EDTA, 0.25% (w/v) Na-deoxycholate, 1 mM Na$_2$VO$_4$, 1 mM NaF, 1% (v/v) NP-40 (nonyl phenoxypolyethoxylethanol), 1 mM PMSF (phenylmethylsulfonyl fluoride) and protease inhibitors consisting 10 µg/ml each of chymostatin, leupeptin, pepstatin and antipain). Insoluble debris was removed by centrifugation and the supernatants were incubated with GTPase effector coated beads (PAK1-PBD for Cdc42 and Rac1) for 1 h. Primary antibodies directed against Cdc42 or Rac1 and secondary antibody Alexa 488 were incubated with the beads for 1 h. Fluorescence intensity MCF (mean channel fluorescence) was used to measure the amount of active intracellular GTPase. MCF was measured by flow cytometry (Accuri C6, BD Biosciences). GTPase activity was
calculated as \( \frac{(MCF_{\text{sample group}} - MCF_{\text{unstimulated negative control}})}{MCF_{\text{stimulated positive control}}} \).

**Quantification of filopodia formation**

The assay was conducted as described previously (23). Cells were cultured on coverslips to 50% confluence and serum-starved for 2 h, treated with individual drugs and stimulated with 10 ng/ml EGF (epidermal growth factor) for 20 min. Cells were gently rinsed 3x with ice cold PBS and fixed with 3% paraformaldehyde. Rhodamine phalloidin was used to label the actin. Images were collected using a Zeiss LSM (laser scanning microscope) 510 confocal microscope equipped with a 63x oil immersion lens. For each experiment, a battlement pattern was used to select 30 images at random. Length and number of filopodia per cell were quantified using Slidebook 5.5 software.

**Cell adhesion assay**

The adhesion assay was modified from the method described by M.J. Humphrie (39). Cells were cultured at least 48 h and disassociated with 0.05% trypsin/EDTA. Suspended cells were rested in 0% FBS media for 1 h and treated with individual drugs. Cells stimulated with 5% serum were seeded on a 96-well plate \((5\times10^4 \text{ cells/well})\) coated with 0.5 µg/cm² fibronectin or collagen and permitted to attach for 1 h. The 96-well plate was gently washed with PBS and cells were fixed with 3% paraformaldehyde. Samples were stained with crystal violet and lysed with 10% acetic acid and absorbance \((\lambda=595\text{nm})\) quantified using on a plate reader.

**Cell migration assay**

SKOV3ip cells were plated at \(1\times10^5 \text{ cells/well}\) in 24-well Boyden chambers and allowed to attach for 4 h. Ketorolac enantiomers were added to growth media at final concentrations ranging from 1 to 300 µM. After 48 h, inserts were removed and stained.
with DAPI (4’,6-diamidino-2-phenylindole). Membrane filters were imaged on a Zeiss inverted microscope using a 20x objective. Three representative fields were counted from each treatment group.

**Gelatin degradation assay**

The commercial gelatin degradation kit (Millipore) was used per manufacturer’s instructions and modified to incorporate drug treatment and EGF stimulation as follows. Fluorescent gelatin was coated on coverslips as described previously (25). Cells were seeded on fluorescent coverslip and allowed to adhere for 6 h and then treated with individual drugs for 24 h. Cells were fixed with 3% paraformaldehyde, permeabilized with 0.1% Triton X-100 and immunostained for Tks5. Actin was visualized with FITC-phalloidin. Fifteen fields per coverslip were imaged on a Zeiss LSM 510 META with a 63x oil immersion objective. Gelatin degradation by invadopodia was analyzed using Slidebook 5.5 software. Percent degradation was quantified as: (degradation area)/(total cell area) for each image.

**Western blot**

SKOV3ip cells were serum-starved for 2 h and treated with individual drugs for 1 h. After simulation with 10 ng/ml EGF for 20 min, cells were washed with ice cold PBS and lysed with RIPA buffer. Cell lysates were processed for SDS-PAGE, transferred to polyvinylidene fluoride membranes and individual proteins were detected with specific antibodies directed against PAK and phosphor-PAK.

**Statistical analyses**

Prism 5 software (GraphPad) was used to analyze all data to determine statistical significance. One-way ANOVA (Analysis of Variance) with Dunnett’s test for multiple comparisons was performed to compare differences between the means of each group.
relative to the control group for all assays. P-values less than 0.05 were considered statistically significant. For some assays conducted on primary ovarian patient samples (GTPase activity measurements and gelatin degradation assays), standard z-scores of the values were calculated for each patient to minimize large ranges of values and to compare across groups on a uniform scale. ANOVA was performed on these standardized values.

Results

R-ketorolac acts as an allosteric inhibitor of guanine nucleotide binding to Cdc42 and Rac1

The enantiomeric selectivity of ketorolac (Fig. 1A) against Cdc42 and Rac1 was predicted by virtual screening and modeled in docking studies (25). To verify ketorolac inhibition of nucleotide binding activity and determine the mechanism of inhibition, a bead based flow cytometry assay – which measures the in vitro GTPase nucleotide binding activity – was used. First, equilibrium nucleotide binding assays were performed under conditions where the tested compound concentration was held fixed against increasing concentrations of fluorescent nucleotide. In the presence of R-ketorolac, both the maximum fluorescence ($B_{\text{max}}$) and the apparent dissociation constant ($K_d$) of BODIPY-GTP for Cdc42 and Rac1 changed, which suggests a noncompetitive mechanism action (Fig. 1B, 1D, Supplementary Table 2). S-ketorolac did not change the $B_{\text{max}}$ and the $K_d$ for Cdc42 (Fig. 1C, Supplementary Table 2) and exhibited a minor inhibition of Rac1 only at the maximum concentration of 100 µM (Fig. 1E). Single-plex dose-response measurements were used to verify the enantiomer selectivity of ketorolac for inhibiting nucleotide binding by Cdc42 and Rac1. The nucleotide concentrations in the assay were fixed at the determined dissociation constants ($K_d \approx 300$ nM). Increasing
R-ketorolac concentrations reduced BODIPY-GTP binding, with respective EC$_{50}$ (half-maximal effective concentration) values of 1.887×10$^{-5}$ for Cdc42 and 2.308×10$^{-5}$ for Rac1 (Fig. 1F, 1G). The maximal inhibitory response was ~20% for both GTPases. S-ketorolac did not exhibit an inhibitory activity against either GTPase under the tested conditions. Together, these findings suggest an enantiomer-selective, inhibitory activity of R-ketorolac against the nucleotide binding activity of Cdc42 and Rac1. Mechanistically, R-ketorolac action is consistent with an allosteric inhibition of GTPase nucleotide binding.

**R-ketorolac inhibits Cdc42 and Rac1 activation in immortalized and primary human ovarian cancer cells**

We have developed a flow cytometry based assay for quantitatively assessing the levels of active GTPases in cell lysates (38). The assay was used to test the cellular impact of ketorolac isoforms on GTPase activation. Maximal Cdc42 and Rac1 activation in SKOV3ip cells treated with 10 ng/ml EGF occurred at different times; 20 min for Cdc42 and 5 min for Rac1 (Supplementary Fig. S1). Growth factor stimulated activation of Cdc42 and Rac1 was differentially inhibited in an enantiomer-selective manner (Fig. 2A, 2B). R-ketorolac substantially inhibited growth factor dependent activation of Cdc42 and Rac1 in a dose-dependent manner with an EC$_{50}$ value of 2.577 µM for Cdc42 and 0.587 µM for Rac1 (Fig. 2A, 2B, circles). In contrast, even at the highest dose of 100 µM, S-ketorolac exhibited limited inhibition (less than 30% of maximum by R-ketorolac) of Cdc42 and Rac1 (Fig. 2A, 2B, squares). Enantiomer-selective inhibition was also found in HeLa cells treated with R-ketorolac (25). Control cytotoxicity measurements in three different cell lines (SKOV3ip, OVCA 429, and OVCA 433) showed <10% inhibition of cell proliferation induced by either enantiomer of ketorolac at the highest tested dose and treatment time (300 µM for 96 h).
The effect of ketorolac was also examined in primary ovarian cancer cells purified from patient ascites. Surgery samples were obtained and analyzed as part of an approved clinical study (see Materials and Methods and Supplementary Table 1). Primary human ovarian cancer cells were enriched via Ficoll gradient centrifugation and depletion of lymphocytes using CD45 Dynabeads. Purified primary human ovarian cancer cells were positive for CA125 and EpCAM, which are commonly overexpressed in epithelial ovarian carcinomas (Supplementary Fig. S2)(40, 41). Isolated tumor cells were treated with individual ketorolac isoforms or specific Cdc42 and Rac1 inhibitors and the endogenous Cdc42 and Rac1 activities were tested. Due to the heterogeneity in activity levels of the GTPases for individual patient samples, z-scores were used to comparatively evaluate the impact of ketorolac on tumor cell GTPase activities from different patients. Treatment with 10 µM R-ketorolac reproducibly inhibited both Cdc42 and Rac1 in a statistically significant manner. The magnitude of R-ketorolac inhibition of Cdc42 or Rac1 was similar to the inhibition observed in positive controls treated with CID2950007, an allosteric Cdc42 inhibitor, or NSC23766, a Rac1 inhibitor that interferes with GEF (guanine nucleotide exchange factor)-mediated GTPase activation (21, 23). S-ketorolac exhibited limited inhibition and was not statistically significant (Fig. 2C-D).

Taken together, the results demonstrate that R-ketorolac is a potent, enantiomer-selective inhibitor of Cdc42 and Rac1 in primary human ovarian cancer cells.

**Inhibition of Cdc42 and Rac1 by R-ketorolac decreases activation of downstream p21 activated kinases (PAK1/PAK2)**

The impact of R-ketorolac on PAK1/PAK2 effector signaling directly downstream of the Cdc42 and Rac1 GTPases was examined (Supplementary Fig. S3A). Cells stimulated with 10 ng/ml EGF exhibited robust phosphorylation of the Ser144/141 residues compared to unstimulated control cells. In contrast, there was a dose-
dependent suppression of p-PAK1/PAK2 following R-ketorolac treatment that was similar to positive controls treated with Cdc42 or Rac1 specific inhibitors. S-ketorolac on the other hand had limited effect on p-PAK1/PAK2 levels at either 1 µM or 10 µM (Fig. 3A-C). The expression of total PAK1 was not affected by either R- or S-ketorolac treatment (Fig. 3A). These results demonstrate the suppression of p-PAK1/PAK2 paralleled the inhibition of Cdc42 and Rac1 in a dose-dependent manner following R-ketorolac treatment; and S-ketorolac exhibited no significant inhibition of p-PAK1/PAK2.

Phosphorylation of PAK1/PAK2 on two further residues (Thr423/402 or Ser199/204 / Ser192/197) that are downstream of other signaling pathways were also examined. Interestingly, p-PAK1(Thr423)/PAK2(Thr402) and p-PAK1(Ser199/204)/PAK2(Ser192/197) were reduced by R and S-ketorolac with greater variability and less pronounced enantiomeric selectivity (Supplementary Fig. S3A-E). For example, R-ketorolac consistently inhibited the phosphorylation at pPAK1/PAK2 (Thr423) with statistical significance at 1 µM though more variably at 10 µM. S-ketorolac exhibited statistically significant inhibitory effects at 10 µM against Thr432/402, but not against Ser199/204 / Ser192/197. Inhibition of phosphorylation by the Rac1 inhibitor NSC23766 and the Cdc42 inhibitor CID2950007 was also more modest and failed to reach statistical significance in some instances. The explanation for the differences in responsiveness of individual phosphorylation sites is likely due to the fact that Ser144/141 is localized in an N-terminal regulatory domain and directly interacts with Cdc42 and Rac1 (Supplementary Fig. S3A). While Thr423/402 residues in the catalytic kinase domain and Ser199/204/ Ser192/197 adjacent to auto-inhibitory domain (AID) are targeted by other regulatory molecules in a GTPase-independent manner (42, 43). For example, S-ketorolac may inhibit phosphorylation on these sites by affecting lipid-dependent stimulation of PAK1/PAK2 (e.g. sphingosine) or through crosstalk between
COX-1/COX-2 and PI3K (phosphatidylinositol-4,5-bisphosphate 3-kinase)-GTPase-PAK1/PAK2 (44, 45).

**R-ketorolac inhibits Cdc42-dependent filopodia formation in SKOV3ip cells and primary ovarian cancer cells**

Filopodia are membrane protrusions that are constructed of bundled actin filaments and directly regulated by Cdc42 (46). Therefore, we tested filopodia formation, including numbers and length of filopodia to evaluate the effect of ketorolac on cell behaviors. When resting cells were stimulated with 10 ng/ml EGF, both numbers and length of filopodia increased with the most striking activation seen 20 min post-stimulation. Two concentrations of R-, and S-ketorolac were tested to take into consideration differential sensitivities of Cdc42 to the two enantiomers. In comparison to the vehicle treatment group, R-ketorolac (at both 1 µM and 10 µM concentrations) decreased numbers length of filopodia to basal levels and similar to CID2950007; while S-ketorolac only showed a significant inhibition on filopodia length at 10 µM and did not significantly inhibit filopodia numbers at either 1 µM or 10 µM. (Fig. 4A-C). These results demonstrate that R-ketorolac impedes filopodia formation, which depends on the upstream activation of Cdc42.

Filopodia formation assays performed using primary ovarian cancer cells yielded similar results and reinforced the finding of the enantiomer-selective effect. R-ketorolac treated primary ovarian cancer cells exhibited significantly decreased filopodia numbers and length; while S-ketorolac exerted no inhibitory effect (Fig. 4D-F).

**R-ketorolac inhibits Cdc42- and Rac1-mediated cell adhesion, migration and invasion**
**Cell adhesion** - Cdc42 and Rac1 are involved in cellular signaling pathways that transduce extracellular signals to the assembly of integrin-mediated focal adhesion complexes (47). The process of cell-substrate adhesion plays critical roles during cancer metastasis which is required for the anchoring of malignant spheroids to the extracellular matrix (ECM) of target abdominal organs (4). A cell attachment assay was used to test the effect of ketorolac on cell adhesion. Stimulated cells were allowed to adhere to matrix-coated substrates. R-ketorolac reduced SKOV3ip cells adherence to both fibronectin and collagen, and S-ketorolac had no significant effect (Fig. 5A-B). R-ketorolac also inhibited human primary ovarian cancer cell adhesion to collagen; while S-ketorolac had no significant effect (Fig. 5C). This observation suggests that the R-enantiomer of ketorolac inhibits cell-substrate adhesion likely as a biological consequence of its inhibitory effect on upstream Cdc42 and Rac1 activation.

**Cell migration** - Activated by extracellular stimuli and dependent on GTPase activation, cell migration is initiated by the formation of membrane protrusions, including Cdc42-dependent filopodia and Rac1-mediated lamellipodia (7). SKOV3ip cell migration in the presence of R- or S-ketorolac was tested in a Boyden chamber assay. Migration was inhibited in a dose dependent manner with R-ketorolac beginning to impinge on cell migration at 1 µM. The inhibitory effect increased in a dose-dependent manner with maximum inhibition of ~80% at 300 µM R-ketorolac (Fig. 5D). Modest inhibition by S-ketorolac was detected at about 50 µM with a maximum inhibition less than 50% at 300 µM. The results demonstrate that cell migration was inhibited as a direct biological consequence mediated by Cdc42 and Rac1 inhibition by R-ketorolac, whereas S-ketorolac was 50-fold less potent.

**Invasion** - Invadopodia are membrane protrusions that are dependent on activated Cdc42 and Src kinase. Invadopodia concentrate matrix metalloproteinases at their tips
and based on their matrix degradative properties serve as surrogates for cell invasive behaviors (48). To study the effect of ketorolac on invadopodia formation, the invadopodia-dependent degradation of gelatin matrices was quantified. In Skov3ip cells, invadopodia were observed as puncta of F-actin and Tks5 positive structures, which colocalized with the degradation sites on the gelatin matrix (Fig. 6A). R-ketorolac treatment also resulted in reduced gelatin degradation in a dose-dependent manner with 70-80% inhibition at 1 and 10 µM. However, S-ketorolac did not exert any obvious inhibition of gelatin degradation at 1 µM and the reduction of gelatin degradation with 10 µM S-ketorolac treatment was ~50% but failed to reach the statistical significance (Fig. 6B, D). Tks5 is an early marker of invadopodia formation that precedes matrix metalloprotease localization to the tips of mature structures. To distinguish if R-ketorolac had a direct inhibitory effect on metalloproteinase activity or if the observed effect on gelatin degradation was primarily due to inhibition of invadopodia formation, the impact on metalloprotease activity secreted into the culture medium was also measured and found to be similar +/- ketorolac. Therefore, we conclude that the primary effect of R-ketorolac is to prevent Cdc42-dependent invadopodia formation. When the gelatin degradation assay was conducted in primary ovarian cancer cells, the standardized z-scores showed the degradation of matrix by tumor cells was also significantly decreased in a dose dependent manner by R-ketorolac treatment, while the inhibition by S-ketorolac was less and reached significance only at the highest dose (Fig. 6C, 6E). Z-scores were used to account for large differences in absolute GTPase activity levels observed for individual patient samples (Fig. 2C, 2D), likely related to known differences in GTPase overexpression seen in ovarian cancer (11, 12). The inhibitory effect of R-ketorolac in primary ovarian cancer cells is consistent with the observations in SKOV3ip cells.
Discussion

In the present study, we establish R-ketorolac as an allosteric, non-competitive inhibitor of guanine nucleotide binding to Cdc42 and Rac1. In its clinical application, ketorolac is given for its potent analgesic activity. It is administered as a racemic mixture via diverse routes (intravenous, injectable, oral, intranasal) and is known as Toradol™. The pain relieving activity is ascribed primarily to the S-enantiomer, which is a known non-selective cyclooxygenase (COX-1/COX-2) inhibitor (27, 28). The R-enantiomer lacks significant activity against cyclooxygenases (e.g. IC<sub>50</sub> >100 µM against COX1 and COX2 and ~3 orders of magnitude greater than the IC<sub>50</sub> of S-ketorolac) and has until now been considered inert (27, 28). The previously unrecognized and novel mechanism of action for the R-enantiomer has important ramifications when considering the efficacy and novel activities of clinically administered ketorolac. For example, breast cancer patients treated with ketorolac perioperatively had a decreased rate of early breast cancer relapse (6). Our own studies demonstrate ovarian cancer patients receiving ketorolac exhibit an enrichment of R-ketorolac in the peritoneum, a reduction in GTPases activation of residual tumor cells, and improved 5-year survival (12). The cell based studies using human immortalized and primary human ovarian cancer cells presented here, demonstrate that R-ketorolac treatment alters tumor cell adhesion, migration and invasion—all behaviors that are central to ovarian cancer metastasis. The findings offer unprecedented mechanistic insights regarding the R-ketorolac activity against GTPases, which may explain the clinically observed survival benefit in patients treated perioperatively with racemic ketorolac.
The biochemical basis for GTPase inhibition by R-ketorolac is provided by computational and experimental approaches. A model of R-ketorolac docked near the GTPase nucleotide binding pocket was generated based on DOCK9 GEF facilitated nucleotide exchange on Cdc42 (25, 49) and is consistent with the observed allosteric, non-competitive inhibition mechanism in the present studies. We suggest that the activity of R-ketorolac against Cdc42 and Rac1 GTPases may result from a similar magnesium exclusion mechanism, except with magnesium exclusion being induced by the carboxyl moiety at the chiral center of R-ketorolac instead of by Val1951 on DOCK9 GEF. The consequent reduced stabilization of bound nucleotide by such magnesium exclusion could reduce nucleotide binding affinity and promote release when R-ketorolac is present. The model is enantiomer-selective, with S-ketorolac being poorly positioned to exert the same magnesium exclusion and therefore could explain the observed differences in EC₅₀ values measured for R- and S-ketorolac in the in vitro nucleotide binding assay. The model is further supported by X-ray crystallography data, which identified the preferential binding of S-naproxen to COX-2 (50). R-naproxen, like R-ketorolac, exhibits Cdc42 and Rac1 inhibitory activity, albeit with less potency and naproxen, like ketorolac has a constrained alpha methyl carboxyl that may account for the stereo-selective activities of the R- and S-enantiomers (25).

In ovarian cancer, cyclooxygenases are upregulated and have been considered as potential targets, however, clinical trials have been mixed and do not support significant benefit in combinatorial treatment with chemotherapy and a cyclooxygenase inhibitor versus treatment with chemotherapy alone (31). Although the survival benefit of ketorolac use in breast cancer was postulated to be due to possible inhibitory roles in anti-angiogenesis, inhibition of prostaglandin synthesis and decreased immune suppression as compared to opioids and other analgesics (51), there was previously no
precedence for other pharmacologic activities associated with R- or S-ketorolac. We speculate that the slight inhibitory effects of S-ketorolac on GTPase activation and actin dependent cell behaviors may arise from crosstalk between COX-2 and PI3K and integrin regulated pathways. COX-2 dependent crosstalk has been shown through knockout and pharmacologic means to regulate Cdc42 and Rac1 activation, and adhesion and migration of macrophages and endothelia (45, 52). Because R-ketorolac is a much less potent COX inhibitor than S-ketorolac, its more pronounced effect on GTPase activation and downstream cell behaviors indicates that it is primarily targeting Cdc42 and Rac1 through a direct mechanism. Furthermore, pharmacokinetic analyses show that S-ketorolac is more rapidly excreted, leading to an increased prevalence of R-ketorolac in vivo (12, 27, 28). Taken together, our identification of R-ketorolac as a GTPase inhibitor helps to explain the significant benefits of racemic ketorolac in human breast and ovarian cancer patient survival, and why other NSAIDs that preferentially target COX have not yielded similar benefit (6, 12, 32).

Ketorolac is an FDA (Food and Drug Administration)-approved drug for human use and is in active clinical use as the racemic mix. Therefore, R-ketorolac has significant potential for rapid repurposing. Implementation of R-ketorolac in human clinical trials would offer the first opportunity to directly test the predicted benefit of a Cdc42 and Rac1 selective inhibitor for cancer patients. Such an application could circumvent current renal and hematologic toxicities that limit racemic ketorolac use to a maximum of 5 days. Analyses of Rac1 inhibition in cancer cell lines and animal models with NSC23766 treatment suggests benefit for inhibiting metastasis and angiogenesis (53). Additionally, Rac1 inhibition may mitigate Trastuzumab resistance in breast cancer cell lines, thus suggesting that the availability of a clinically accessible selective Cdc42 and Rac1 inhibitors could offer new paradigms for combinatorial therapies (53). We envision that
the use of R-ketorolac in the perioperative window and thereafter presents a unique opportunity to block tumor reseeding and spread, as well as angiogenesis, which may enhance the efficacy of combined chemotherapies or targeted therapies.

Figure Legends

Figure 1. R-ketorolac selectively inhibits Cdc42 and Rac1 GTPase BODIPY-GTP binding as an allosteric inhibitor. (A) Chemical structure of R- and S-ketorolac with chiral center noted. (B-C) The presence of R-ketorolac changed both the $B_{\text{max}}$ and the $K_d$ (values are tabulated in supplementary table 2) of BODIPY-GTP binding to Cdc42 measured under equilibrium binding conditions, while S-ketorolac did not affect BODIPY-GTP binding. (D-E) R-ketorolac changed the $B_{\text{max}}$ and the $K_d$ of BODIPY-GTP binding to Rac1 measured under equilibrium binding conditions, while S-ketorolac did not affect BODIPY-GTP binding except at 100 µM. The equilibrium binding of BODIPY-GTP to the GTPases was measured in the presence of 0.1% DMSO or various concentrations of R- or S-ketorolac (1–100 µM). BODIPY-GTP binding curves were fitted to a hyperbolic one-site binding equation from GraphPad Prism 5. (F-G) R-ketorolac in contrast to S-ketorolac inhibited BODIPY-GTP binding to Cdc42 and Rac1 GTPases in a dose-dependent manner. BODIPY-GTP concentration was fixed at 300 nM for these experiments. The inhibition curves were fitted to the sigmoidal dose-response equation from GraphPad Prism5. In all experiments, GST-Cdc42 or Rac1 were immobilized on GSH beads and used to measure BODIPY-GTP binding. Bead-associated fluorescence intensity was quantified by flow cytometry and used to monitor drug treatment induced changes in nucleotide binding. All experiments were repeated three times independently.

Figure 2. R-ketorolac preferentially inhibits Cdc42 and Rac1 activities in SKOV3ip cells and primary human ovarian cancer cells. (A-B) R-ketorolac causes a dose-dependent, enantiomer selective inhibition of growth factor stimulated Cdc42 and Rac1 activation in SKOV3ip cells. SKOV3ip cells were starved in 0% FBS media for 2 h and
pretreated with individual drugs for 2 h prior to EGF (10 ng/ml) stimulation. Activated
Cdc42 and Rac1 levels in cell lysates were measured using a flow cytometry based
GTPase effector binding assay. Flow intensities were normalized to untreated controls.
All experiments were repeated three times independently. (C-D) R-ketorolac causes a
dose-dependent, enantiomer-selective inhibition of endogenous Cdc42 and Rac1
activities in primary ovarian cancer cells. Isolated primary ovarian cancer cells from three
independent patients were treated with drugs for 1 h and processed for flow cytometry
GTPase effector binding assays to measure the GTPase activity. Six patient samples
were tested for Cdc42 activity and five patient samples were tested for Rac1 activity in
response (Supplementary Table 1). CID2950007 and NSC232766 served as Cdc42 and
Rac1 specific inhibitors respectively. Plotted are z-scores. Quantification of three
independent measurements are plotted ±SEM. Statistically significant differences are
indicated: *p<0.05, **p<0.01, ***p<0.001.

Figure 3. R-ketorolac decreases the phosphorylation of
PAK1(Ser144)/PAK2(Ser141) without affecting total PAK levels. (A) SKOV3ip cells
were cultured overnight, then starved in 0% FBS media for 2 h and pretreated with
individual drugs for 2 h followed by EGF stimulation (10 ng/ml) for 20 min.
Representative blots from one of three independent experiments are shown. Equal
amounts of cell lysate protein were resolved by SDS-PAGE and immunoblotted for p-
PAK1(Ser144)/PAK2(Ser141). GAPDH served as the loading control. Cdc42 inhibitor,
CID2950007 and Rac1 inhibitor, NSC232766 were used as positive controls. (B-C) Films
from three independent experiments were quantified by ImageJ analysis. p-PAK1/PAK2
levels were normalized to unstimulated controls. Quantification of three independent
measurements are plotted ±SEM. Statistically significant differences are indicated:
*p<0.05, **p<0.01, ***p<0.001.
Figure 4. R-ketorolac decreases Cdc42 dependent filopodia formation in SKOV3ip cells and primary human ovarian cancer cells following EGF stimulation. (A) Representative confocal images of filopodia formation for each treatment group in SKOV3ip cells are shown. Lower panels are magnified images of the boxed regions. (B-C) Quantification of numbers and length of filopodia on each cell. (D) Representative confocal images of filopodia formation for each treatment group in primary human ovarian cancer cells are shown. Lower panels are magnified images of the boxed regions. (E-F) Quantification of numbers and length of filopodia per cell in primary human ovarian cancer cells. For all experiments, cells were plated on coverslips and cultured overnight, then starved in 0% FBS media for 2 h and pretreated with drug or 0.1% DMSO vehicle for 2 h, followed by EGF (10 ng/ml) stimulation for 20 min. Cells were permeabilized and stained with rhodamine-phalloidin. Confocal images were taken on a Zeiss LSM 510 META confocal microscope. All quantification is based on three independent trials with 30 cells imaged in a battlement pattern and analyzed using Slidebook 5.5 software. Mean lengths or numbers of filopodia are plotted ±SEM. Statistically significant differences are indicated: *p<0.05, **p<0.01, ***p<0.001.

Figure 5. R-ketorolac inhibits cell-substrate adhesion and migration in SKOV3ip cells and primary human ovarian cancer cells. (A-B) R-ketorolac significantly inhibits cell adhesion in SKOV3ip cells compared to S-ketorolac. SKOV3ip cells were trypsinized, starved in 0% FBS media for 1 h, pretreated with drug for 1 h, followed by serum stimulation (5% (v/v) final concentration) and seeded on matrix pre-coated 96-well plate for 1 h. Cells were fixed and stained with crystal violet and finally lysed with acetic acid. Cell substrate adhesion was quantified based on absorbance of cell lysates at 595 nm and normalized to unstimulated controls. (C) Similar to SKOV3ip cells, R-ketorolac...
significantly inhibits cell substrate adhesion in primary human ovarian cancer cells as well. Primary ovarian cancer cells were purified, cultured and used for the cell attachment assays to test the effect of drugs on cell substrate adhesion. CID2950007 and NSC23766 served as positive controls. Each group was normalized to unstimulated controls. (D) R-ketorolac inhibits cell migration in a dose-dependent manner with maximal inhibition of 80% in SKOV3ip cells, whereas S-ketorolac is 50-fold less potent. SKOV3ip cells were seeded in Boyden chambers in the presence of drug for 48 h. Cell migration was normalized to no treatment controls. Three fields of view were counted for each treatment group. Data represented three independent trials. Each data point represents the mean of measured values ±SEM. Statistically significant differences are indicated: *p<0.05, **p<0.01, ***p<0.001.

**Figure 6. R-ketorolac inhibits invadopodia formation and gelatin degradation in SKOV3ip and primary human ovarian cancer cells.** (A) Colocalization of gelatin degradation, actin and Tks5 antibody in SKOV3ip cells. Insets are magnified images of the boxed regions. Arrowheads denote points of invadopodia formation that are coincident with gelatin degradation. (B) Representative confocal images of gelatin degradation for each treatment group in SKOV3ip cells are shown. Lower panels are magnified images of the boxed regions. Arrowheads denote the gelatin degradation sites. (C) Representative confocal images of gelatin degradation for each treatment group in primary ovarian cancer cells are shown. Lower panels are magnified images of the boxed regions. Arrowheads denote the gelatin degradation sites. (D) Quantification of the gelatin degradation area in SKOV3ip cells. (E) Quantification of the gelatin degradation area in primary ovarian cancer cells. Due to the variability of the extent of gelatin degradation observed with primary human ovarian cancer cells, z-scores are plotted. For all experiments, SKOV3ip cells or primary ovarian cancer cells were seeded
on Cy3-gelatin labeled coverslips for 24 h in the presence of different drugs, including two enantiomers of ketorolac, and Cdc42 and Rac1 specific inhibitors (CID2950007 and NSC23766, respectively) as positive controls. DMSO (0.1%) served as the vehicle control treatment. All quantification is based on three independent trials with 15 representative fields counted for each treatment. Statistically significant differences are indicated: *p<0.05, **p<0.01, ***p<0.001.
