ABSTRACT

Alectinib is used as a first-line treatment for anaplastic lymphoma kinase (ALK)-rearranged non–small cell lung cancer (NSCLC). Whereas other ALK inhibitors have been reported to be involved in resistance to ATP-binding cassette (ABC) transporters, no data are available regarding the association between resistance to alectinib and ABC-transporters. To investigate whether ABC-transporters contribute to alectinib resistance, ABC-transporter expression in alectinib-resistant cell lines derived from a patient with ALK-rearranged NSCLC and from H2228 lung cancer cells was evaluated and compared with that in each parent cell type. ATP-binding cassette subfamily C member 11 (ABCC11) expression was significantly increased in alectinib-resistant cell lines compared with that in alectinib-sensitive lines. ABCC11 inhibition increased sensitivity to alectinib in vitro. ABCC11-overexpressing cells were established by transfection of an ABCC11 expression vector into H2228 cells, while control cells were established by transfecting H2228 cells with an empty vector. ABCC11-overexpressing cells exhibited decreased sensitivity to alectinib compared with that of control cells in vitro. Moreover, the tumor growth rate following alectinib treatment was higher in ABCC11-overexpressing cells than that in control cells in vivo. In addition, the intracellular alectinib concentration following exposure to 100 nmol/L alectinib was significantly lower in the ABCC11-overexpressing cell line compared with that in control cells. This is the first preclinical evidence showing that ABCC11 expression may be involved in acquired resistance to alectinib.

Introduction

In 2007, a novel oncogene, EML4–ALK fusion gene, in which the echinoderm microtubule-associated protein-like 4 (EML4) gene is fused to the anaplastic lymphoma kinase (ALK) gene, was identified in patients with non–small cell lung cancer (NSCLC; refs. 1, 2). Notably, the second-generation ALK inhibitor, alectinib, showed superior efficacy in primary treatment of ALK-positive NSCLC compared with that of crizotinib, a first-generation ALK inhibitor (3, 4). However, although alectinib is used as the first-line treatment for ALK-positive NSCLC, approximately 30% of patients treated with alectinib become refractory within a year of treatment owing to acquired resistance (4).

Several mechanisms of resistance to molecular-targeted therapeutic agents have been reported including: mutations of the drug target; activation of bypass signaling pathways; dysregulation of apoptosis; tumor microenvironment including the extracellular matrix, immune and inflammatory cells, and blood vessels; and increased protein expression of drug efflux pumps such as ATP-binding cassette (ABC) transporters (5). Previous studies showed that the presence of secondary mutations such as H1717T/N/S, V1180L, L1196M, and G1202R in the kinase domain of ALK conferred resistance to alectinib (6, 7). Another major resistance mechanism involves bypass salvage signaling that maintains downstream signaling pathways to activate survival, antiapoptotic, and proliferation signals. In particular, activation of EGFR has reported to maintain survival signaling that induces alectinib resistance, and we have reported that coactivation of c-Src and MET functions as signaling that under alectinib exposure (8, 9).

ABC-transporters transport various molecules and are involved in multidrug resistance to anticancer agents. In particular, nine ABC-transporters, that is, multidrug resistance protein 1/ABCB1 (ABCB1), multidrug resistance-associated protein 1 (MRP1)/ABCC1 (ABCC1), MRP2/ABCC2 (ABCC2), MRP3/ABCC3 (ABCC3), MRP4/ABCC4 (ABCC4), MRP5/ABCC5 (ABCC5), MRP7/ABCC9 (ABCC9), MRP8/ABCC11 (ABCC11), and breast cancer resistance protein/ABCG2 (ABCG2) have been reported to be associated with anticancer drug resistance (10, 11). Moreover, several tyrosine kinase inhibitors (TKI; e.g., imatinib, nilotinib, dasatinib, ponatinib, gefitinib, erlotinib, lapatinib, vandetanib, sunitinib, and sorafenib) were recently reported as substrates for ABC-transporters including ABCB1, ABCC1, ABCG2, and ABCG2 (12). Notably, overexpression of ABCB1 was shown to be involved in the resistance to crizotinib and ceritinib, which constitute other ALK-TKIs, but not to alectinib (13). In addition, it was demonstrated that alectinib is not a substrate for ABCB1 and ABCG2 (14, 15). Thus, unlike other TKIs, the association between alectinib resistance and ABC-transporter expression is not fully understood. Therefore, the aim of this study was to determine the ABC-transporters that are associated with alectinib resistance in lung cancer.

We previously reported the establishment of a clinical paired resistant model (CPRM) comprised of patient-derived ALK-
rarranged NSCLC cell lines from a treatment-naïve and subsequently, alectinib-refractory patient (9). In this study, we evaluated the expression of the nine chemoresistance-associated ABC-transporters in these cells, identifying that ABCC11 expression was significantly increased in alectinib-resistant cells compared with that in alectinib-sensitive cells. Therefore, in this study we investigated whether increased ABCC11 expression may constitute a mechanism underlying the acquired resistance to alectinib.

Materials and Methods
Clinical information and procedures for obtaining informed consent
The study protocol was prepared in accordance with the Declaration of Helsinki and approved by the Kyoto University Graduate School and Faculty of Medicine Ethics Committee (Kyoto, Japan; certification number: R0996). The patient provided written informed consent to participate in this study.

Establishment of patient-derived lung cancer cells
KTOR1 and KTORI-RE (EML4-ALK variant 1 E13; A20) cells were established from a 29-year-old female patient with ALK-rearranged NSCLC, who regularly visited Kyoto University Hospital (Kyoto, Japan). The method used to establish the patient-derived cells was described previously (9). Briefly, 200 mL of pleural effusion was obtained from the patient with ALK-rearranged lung cancer. Tumor cells were separated by centrifugation at 800 rpm for 5 minutes, and then cultured and maintained in alectinib-free RPMI1640 Medium (Nacalai Tesque) supplemented with 8% heat-inactivated FBS (Sigma-Aldrich) and 1% penicillin/streptomycin (Gibco) at 37.0 °C in 5% CO₂. Information about the patient was obtained from electrical medical records at Kyoto University Hospital (Kyoto, Japan).

Cells and reagents
NCI-H2228 (EML4-ALK variant 3a/b E6; A20) lung cancer cells were purchased in 2016 from ATCC. The alectinib-resistant H2228-AR15 cells were established by exposing NCI-H2228 cells to 300 nmol/L alectinib for 3 months in vitro. Similarly, KTOR1-AR was established from KTOR1 via exposure to 30 nmol/L alectinib for 6 months in vitro. All experiments were performed with cells that were within 20 passages. In 2019, all cells were confirmed to be negative for Mycoplasma using the MycoAlert Mycoplasma Detection Kit (Lonza). Alectinib was kindly provided by Chugai Pharmaceutical Co., Ltd. Crizotinib and ceritinib were purchased from LC Laboratories, and lorlatinib and brigatinib were purchased from ChemScene. Alectinib, crizotinib, ceritinib, and lorlatinib were dissolved in DMSO (Nacalai Tesque) at a concentration of 5 mmol/L and brigatinib was dissolved in DMSO (Nacalai Tesque) at a concentration of 3 mmol/L. DMSO was also used as a vehicle control.

Cell viability and drug susceptibility assay
Cells were cultured overnight in 96-well plates at a density of 5,000 cells/well and treated with increasing concentrations of the reagents or vehicle control medium for 72–168 hours. Subsequently, cells were incubated with CellTiter-Glo 2.0 Luminescent Cell Viability Assay (Promega) for 20 minutes and luminescence was measured using an ARVO X3 Plate Reader (PerkinElmer). The IC₅₀ value was calculated using a nonlinear regression model with a sigmoidal dose response using GraphPad Prism 8.0 (GraphPad software). Three independent experiments were conducted.

Establishment of ABCC11-overexpressing H2228 cells
The ABCC11 expression vector (ABCC11/pcDNA3.1/V5-His) and empty vector (pcDNA3.1/V5-His) were purchased from Invitrogen. The vector map of ABCC11/pcDNA3.1/V5-His was shown in Supplementary Data S2. H2228 cells were transfected with the ABCC11 expression vector or empty vector using NEPA21 electroporator (Nepa Gene) in serum-free Opti-MEM (Thermo Fisher Scientific) to generate stably expressing cells. At 24 hours after transfection, cells were selected and cloned by limiting dilution in a medium containing geneticin selective antibiotic (Wako) for 2–3 weeks. Proteins were extracted from each clone and ABCC11 expression was analyzed by immunoblotting. Once increased expression of ABCC11 was confirmed, two cell lines derived from the transfected cells were selected as ABCC11-overexpressing cells (ABCC11a and ABCC11b). In the same manner, cells transfected with the empty vector were cloned and one cell line that exhibited similar ABCC11 expression as the parent cells was selected as the control cell line (mock).

Intracellular concentration measurement
Cells were cultured overnight in a low attachment 24-well plate (Greiner Bio-One) at a density of 2.5 × 10⁴ cells/well and treated with 100 nmol/L alectinib for 2 and 4 hours. After washing the cells twice with cold PBS, cells were lysed with 50 μL 0.1 mol/L sodium hydroxide solution (Nacalai Tesque) and homogenized. After

Immunoblotting
SDS-PAGE and immunoblotting were performed as described previously (16). Briefly, antibodies against ABCC11 and GAPDH were purchased from Invitrogen. pALK (pY 1604) and secondary antibodies were purchased from Cell Signaling Technology. β-actin was purchased from Sigma-Aldrich (details are provided in Supplementary Table S1). Antibodies against ABCC11 (1:2,000), GAPDH (1:10,000), pALK (1:1,000), and β-actin (1:10,000), and secondary (1:2,000) antibodies were dissolved in 2.5% BSA/TBS with Tween 20. BSA was purchased from Nacalai Tesque. Quantification of protein bands was performed using ImageJ software (https://imagej.nih.gov/ij/).

Quantitative reverse transcription-PCR
Total RNA was extracted from cultured cells using the PureLink RNA Mini Kit (Thermo Fisher Scientific). Gene expression was evaluated by quantitative reverse transcription-PCR (qRT-PCR) using 100 ng of total RNA, the TaqMan RNA-to-Ct 1-Step Kit (Applied Biosystems), and a primer pair. A list of the primers purchased from Thermofisher Scientific is shown in Supplementary Table S2. Reactions were quantified using the 7300 Real-Time PCR System (Applied Biosystems).

Transfection with siRNA
ABCC11 siRNA oligonucleotides were purchased from Thermo Fisher Scientific (Stealth RNAi siRNA; Supplementary Table S3). A total of 3.0 × 10⁴ cells were transfected with siRNA oligonucleotides at a final RNA concentration of 21 nmol/L using Lipofectamine RNAiMAX Transfection Reagent (Invitrogen). The reverse transfection method was performed according to the manufacturer’s protocol. RNA and total protein were extracted at 30 and 54 hours, respectively, following transfection. In the cell viability assay, transfected cells (5,000 cells/well) were cultured in a 96-well plate for 24 hours and treated with increasing concentrations of alectinib for 168 hours. Cell viability was assessed as described above.
incubating the cells at 37°C for 1 hour, cells were neutralized with 50 μL of 0.1 mol/L hydrochloric acid solution (Nacalai Tesque). Alectinib concentration was measured using a Shimadzu Prominence HPLC System (MD) and Qtrap 5500 Quadrupole Mass Spectrometer (AB Sciex). Mass spectrometry analysis was performed using electrospray ionization in positive ion mode. The multiple reaction monitoring mode m/z transition values were set at 483.22–396.10 for alectinib and 491.30–396.10 for d-alectinib as the internal standard.

Xenograft models
Six-week-old female BALB/c-nu mice (CAnN.Cg-Foxn1nu/CrlCrlj) were purchased from Charles River Laboratories. Xenograft models were generated by suspending 1–3 × 10^6 cells in Matrigel (Corning), which was injected subcutaneously into the backs of the mice. Mice with a tumor volume of 80–240 mm^3 were randomly assigned to either alectinib or vehicle groups (day 0). Mice were treated with alectinib (8 mg/kg/day) or vehicle via oral gavage. Tumor volumes were evaluated using digital caliper measurements and calculated using the formula (length/width)_2, where length and width represented the larger and smaller diameters, respectively. The mice were euthanized on day 11. For immunoblotting, mice with a tumor volume of 500–1,500 mm^3 were treated with alectinib (8 mg/kg/day) and were humanely sacrificed 24 hours after alectinib treatment. Tumor tissues were collected, and immunoblotting was performed as mentioned above. All animal experiments and protocols were approved by the Animal Research Committee of Kyoto University (Kyoto, Japan; ID: MedKyO 18298) and implemented according to the ARRIVE guidelines.

Statistical analysis
Continuous variable data are expressed as the means ± SEM. The significance of differences was assessed using the Student t test. Sidak multiple comparison test and Holm–Sidak multiple comparison test were used to compare the mean of more than three groups. P < 0.05 was defined as significant. All statistical analysis was performed using JMP Pro version 12.0 (SAS Institute) and visualized by GraphPad Prism 8.

Results
Establishment of alectinib-resistant cells
We established KTOR1 cells using cells derived from an alectinib-naïve patient with ALK-rearranged NSCLC, and KTOR1-RE cells were established from the same subsequently alectinib-refractory patient (ref. 9; Fig. 1A). The H2228-AR1S and KTOR1-AR cells were established from the H2228 and KTOR1 cells, respectively, through exposure to alectinib to investigate the determinants of acquired resistance in lung cancer. KTOR1-RE, KTOR1-AR, and H2228-AR1S cells were more resistant to alectinib compared with the parental cells.

Figure 1.
ABCC11 as a potential candidate transporter associated with alectinib resistance. A, Schematic representation of establishment of patient-derived alectinib-resistant tumor cells (KTOR1-RE). Pleural effusion from a patient with ALK-rearranged NSCLC was obtained at disease progression and collected cancer cells were cultured in vitro. B, Schematic representation of conventional alectinib-resistant cells (H2228-AR1S and KTOR1-AR). H2228-AR1S cells were established by exposing parental H2228 cells to 300 nmol/L alectinib for 3 months. The KTOR1-AR cells were established by exposure of KTOR1 cells to 30 nmol/L alectinib for 6 months. C, Cell viability assay of KTOR1, KTOR1-RE, and KTOR1-AR (left) or H2228 and H2228-AR1S (right) cells treated with alectinib for 72 hours. P values were calculated using two-way ANOVA. Sidak multiple comparisons test (n = 5). D, Integrated results of the qRT-PCR analysis in the five cell types. Volcano plot representing gene expression of the ABC-transporters. For each gene, the fold change of alectinib-resistant cells (KTOR1-RE, KTOR1-AR, and H2228-AR1S) compared with that of parental cells (KTOR1 and H2228; horizontal line) and significance between alectinib-resistant (n = 3) and parental cells (n = 2) calculated using the t test [−log(P value); vertical line] was plotted. Expression of ABCB1 and ABCC11 was significantly increased in resistant cells (plotted in red). E, ABCC11 protein expression of the five cell types was confirmed by immunoblotting. N.S., not significant.

Expression levels of ABC-transporters in alectinib-resistant cells

To identify transporters that conferred resistance to alectinib, ABC-transporters exhibiting increased expression in alectinib-resistant cells were explored. In particular, gene expression of the nine ABC-transporters previously reported to be related to anti-cancer drug resistance was screened in the five cell types, and the expression ratio (resistant cells/parental cells) of the transporters was calculated (10–12). For each ABC-transporter, the fold change in gene expression (horizontal line) and significance between parental and alectinib-resistant cells calculated using the t test [−log10(P value); vertical line] was plotted (Fig. 1D; Supplementary Fig. S4). Among the transporters, the expression of ABCB1 and ABCC11 genes was significantly increased in the resistant cells (fold change > 1.5; P < 0.05). We focused on ABCC11 as a potential transporter candidate for alectinib resistance, as previous studies suggested that ABCB1 was not involved in the extracellular efflux of alectinib (14, 15).

ABCC11 inhibition sensitizes H2228-AR15 and KTOR1-RE cells to alectinib

Cell viability in the presence of alectinib during siRNA inhibition of the ABCC11 gene was measured to evaluate the functional role of ABCC11 overexpression in alectinib resistance. H2228-AR15 cells transfected with siRNA targeting the ABCC11 gene exhibited reduced cell viability of alectinib compared with that of cells transfected with negative control siRNA (Fig. 2C; Supplementary Table S5). KTOR1-RE cells transfected with siRNA targeting the ABCC11 gene also demonstrated reduced cell viability following alectinib exposure (Fig. 2F; Supplementary Table S6).

ABCC11 overexpression confers alectinib resistance

To investigate whether ABCC11 overexpression induced alectinib resistance, the ABCC11 expression vector (ABCC11/pcDNA3.1/V5-His) was transfected into H2228 cells to establish two ABCC11-overexpressing cell lines, ABCC11a and ABCC11b. H2228 cells were also transfected with an empty vector (mock). Expression levels of the ABCC11 gene and protein were increased in both ABCC11a and ABCC11b cells compared with those in mock cells (Fig. 3A and B). The negative impact of alectinib on cell viability was decreased in ABCC11a and ABCC11b cells compared with that on mock cells (Fig. 3C; Table 2). The loss of cell viability from crizotinib, ceritinib, lorlatinib, and brigatinib exposure was also significantly lower in ABCC11a and ABCC11b cells compared with that in mock cells (Fig. 3D).

ABCC11 overexpression decreases the intracellular alectinib concentration

To obtain evidence supporting that ABCC11 effluxes alectinib, we measured the intracellular accumulation of alectinib in ABCC11a or mock cells using LC/MS. Following treatment with 100 nmol/L alectinib for 2 and 4 hours, the intracellular concentration of alectinib was significantly lower in ABCC11a cells compared with that in mock cells (Fig. 3E; Supplementary Fig. S5). To evaluate the effect of alectinib treatment on ABCC11-overexpressing cells, ALK phosphorylation was evaluated by immunoblotting in cells treated with increasing concentrations of alectinib. Treatment of cells with 10 and 30 nmol/L alectinib suppressed ALK phosphorylation in mock but not ABCC11a cells (Fig. 3F).

In vivo effect of ABCC11 overexpression on alectinib response

To determine whether ABCC11 overexpression might alter sensitivity to alectinib in vivo, xenograft models using H2228 cells transfected with the ABCC11 expression vector and cells transfected with empty vector were established and randomized into two groups: alectinib treatment and vehicle. The dosage of alectinib was selected as 8 mg/kg (10 days) in accordance with the human dose (600 mg/day/body); ref. 17). The tumor growth rate following alectinib treatment was higher with H2228 cells transfected with ABCC11 expression vector compared with that from cells containing empty vector (~34% for ABCC11a, ~24% for ABCC11b, and ~77% for mock; Fig. 4A; Supplementary Fig. S6) and did not affect body weight (Fig. 4B). ALK phosphorylation after alectinib treatment in tumors established from ABCC11a and ABCC11b cells was not suppressed, but those in mock cells was suppressed (Fig. 4C). These results suggested that ABCC11 overexpression could reduce the tumor response to alectinib treatment in vivo.

Discussion

The results of this study showed that ABCC11 expression was increased in alectinib-resistant cells compared with that in the parental cells. We also revealed that altered ABCC11 expression affected the cell viability following alectinib exposure. This is the first report to demonstrate that ABCC11 overexpression may represent a mechanism involved in acquired resistance to alectinib.

ABCC-transporters transport various molecules from the interior to the exterior of the cell. ABCC11 was identified as an ABC-transporter in 2001 (18–20) and is expressed in various tissues...
including the brain, lung, liver, kidney, and apocrine glands (21–24). ABCC11 is also involved in the intracellular to extracellular efflux of dehydroepiandrosterone 3-sulfate, methotrexate, and tenofovir (25, 26), and is a substrate for cytotoxic anticancer agents including 5-fluorouracil and pemetrexed (19, 20, 27). However, to the best of our knowledge, molecular-targeted therapeutics have not previously been described as potential substrates for ABCC11. In this study, we showed that H2228 cells transfected with an ABCC11 expression vector exhibited a lower intracellular alectinib concentration compared with that of cells transfected with negative control siRNA. Cell viability assay of H2228-ARIS (C) and KTOR1-RE cells (F) transfected with ABCC11 siRNA and negative control siRNA then treated with alectinib for 168 hours following 24-hour transfection. Statistical significance was calculated using two-way ANOVA followed by Sidak multiple comparisons test (n = 5). N.S., not significant.

Funazo et al.

Figure 2.
Improved alectinib sensitivity in H2228-ARIS cells transfected with ABCC11 siRNA. Gene expression of ABCC11 following siRNA knockdown of ABCC11 using two different ABCC11-directed RNAi sequences (ABCC11-a and ABCC11-b) in H2228-ARIS (A) and KTOR1-RE cells (D). P-values were calculated using one-way ANOVA and the Dunnett test (n = 4). ABCC11 protein expression detected using immunoblotting in H2228-ARIS (B) and KTOR1-RE cells (E) transfected with ABCC11 siRNA was decreased compared with that in cells transfected with negative control siRNA. Cell viability assay of H2228-ARIS (C) and KTOR1-RE cells (F) transfected with ABCC11 siRNA and negative control siRNA then treated with alectinib for 168 hours following 24-hour transfection. Statistical significance was calculated using two-way ANOVA followed by Sidak multiple comparisons test (n = 5). N.S., not significant.
in other patients. We aim to continue to accumulate evidence to support our model using CPRM.

ABC-transporters are known to cause multidrug resistance (12, 19, 20). In this study, the sensitivity of crizotinib, ceritinib, lorlatinib, and brigatinib was lower in H2228-AR1S cells compared with that in H2228 cells (Supplementary Fig. S8). These results revealed that H2228-AR1S cells exhibit cross-resistance to other ALK inhibitors. In addition, as with alectinib, the cell viability impairment upon exposure to ALK inhibitors was decreased in H2228 cells transfected with the ABCC11 expression vector compared with that of cells transfected with empty vector (Fig. 3D). Although we were unable to measure the intracellular concentration of ALK inhibitors other than alectinib in cells transfected with the ABCC11 expression vector, these findings suggest that ABCC11 expression may be involved in the acquired resistance to multiple ALK inhibitors.

As we were unable to clarify the mechanism underlying ABCC11 overexpression in resistant cells, it is unclear whether exposure to alectinib selects cells with high expression of ABCC11 prior to treatment or induces increased expression of ABCC11 in these cells. Previous studies showed that cancer stem cells (CSC), which are innately resistant to many standard therapies, are associated with overexpression of ABCB1 and ABCG2 (5, 10, 28, 29). In particular, CD44 constitutes a CSC marker that exhibits strong negative correlations with patient survival and has been associated with the expression of ABC-transporters, most notably ABCG2 (5, 28). ABCB1 overexpression was also reported to be associated with short survival in stage 1 lung adenocarcinoma and rendered CSC-like properties (30, 31). These reports indicated that cancer cells may highly express ABC-transporters prior to treatment and that clonal selection of cells with high expression of ABC-transporters

might be associated with acquired resistance to anticancer agents. Although an association between ABCC11 and CSC-like properties has not been reported, clonal selection of ALK fusion gene–positive lung cancer cells with ABCC11 overexpression may represent a mechanism of acquired resistance to alectinib.

Overall, our findings provide new insight into the mechanisms underlying alectinib resistance in ALK-rearranged NSCLC. We found that ABCC11 expression was significantly increased in cells derived from an alectinib-refractory patient using CPRM. We propose that alectinib may constitute a substrate for ABCC11 and that overexpression of ABCC11 may represent an important determinant of acquired resistance to alectinib, although other resistance mechanisms, including activation of salvage signaling pathways, may also be involved. Further studies are required to elucidate the mechanisms of alectinib resistance using CPRM to overcome the problem of acquired resistance in lung cancer.

Quantification of protein bands was performed using ImageJ software. Quantification values for each band were first normalized to corresponding values of β-actin. Then, the ratio between normalized values for ABCC11-overexpressing cells and mock cells was calculated. D, Schematic of ABCC11 role in alectinib resistance. ABCC11 overexpression reduces alectinib intracellular concentrations and attenuates the effects of alectinib. N.S., not significant.
